### Why are there so many?

- Different physical nature of storage devices
  - Ext3 is optimised for magnetic disks
  - JFFS2 is optimised for flash memory devices
  - ISO9660 is optimised for CDROM
- Different storage capacities
  - FAT16 does not support drives >2GB
  - FAT32 becomes inefficient on drives >32GB
  - ZFS, Btrfs is designed to scale to multi-TB disk arrays
- Different CPU and memory requirements
  - FAT16 is not suitable for modern PCs but is a good fit for many embedded devices
- Proprietary standards

13

17

- NTFS may be a nice FS, but its specification is closed

## File Allocation Methods · A file is divided into "blocks" - the unit of transfer to storage · Given the logical blocks of a file, what method is used to choose were to put the blocks on disk?

In this lecture we focus on file systems for magnetic

- For comparison, disk-to-buffer transfer speed of a modern

Conclusion: keep blocks that are likely to be accessed

• 8ms worst case for 7200rpm drive

**Contiguous Allocation** → Easy bookkeeping (need to keep track of the starting block and length of the file) ✓ Increases performance for sequential operations  $_{\scriptscriptstyle X}$  Need the maximum size for the file at the time of creation x As files are deleted, free space becomes divided into many small chunks (external fragmentation) Example: ISO 9660 (CDROM FS) (also stored on disk) 17 WUNSW **Dynamic Allocation Strategies** - Disk space allocated in portions as needed - Allocation occurs in fixed-size blocks No external fragmentation → Does not require pre-allocating disk space x Partially filled blocks (internal fragmentation) x File blocks are scattered across the disk Complex metadata management (maintain the collection of blocks for each file)

18

## External and internal fragmentation External fragmentation The space wasted external to the allocated memory regions Memory space exists to satisfy a request but it is unusable as it is not contiguous Internal fragmentation The space wasted internal to the allocated memory regions Allocated memory may be slightly larger than requested memory; this size difference is wasted memory internal to a partition

Pynamic allocation: Linked list allocation

• Each block contains a pointer to the next block in the chain. Free blocks are also linked in a chain.

• Only single metadata entry per file

• Best for sequential files

Disk

Augustion: What are the downsides?

19

Veep a map of the entire FS in a separate table

A table entry contains the number of the next block of the file
The last block in a file and empty blocks are marked using reserved values

The table is stored on the disk and is replicated in memory
Random access is fast (following the in-memory list)

File allocation table

• Issues

- Requires a lot of memory for large disks

• 200GB = 200\*10^6 \* 1K-blocks ==>
200\*10^6 FAT entries = 800MB

- Free block lookup is slow

• searches for a free entry in table

File allocation table disk layout

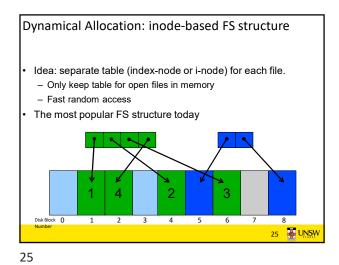

• Examples

- FAT12, FAT16, FAT32

Two copies of FAT for redundancy

i-node implementation issues

• i-nodes occupy one or several disk areas

• i-nodes are allocated dynamically, hence free-space management is required for i-nodes

- Use fixed-size i-nodes to simplify dynamic allocation

- Reserve the last i-node entry for a pointer (a block number) to an extension i-node.

i-node implementation issues

• Free-space management

- Approach 1: linked list of free blocks in free blocks on disk

- Approach 2: keep bitmaps of free blocks and free i-nodes on disk

• Approach 2: keep bitmaps of free blocks and free i-nodes on disk

### Free block list

- List of all unallocated blocks
- · Background jobs can re-order list for better contiguity
- Store in free blocks themselves
  - Does not reduce disk capacity
- Only one block of pointers need be kept in the main memory

Bit tables

26

- Individual bits in a bit vector flags used/free blocks
- 16GB disk with 512-byte blocks --> 4MB table
- May be too large to hold in main memory
- Expensive to search
  - Optimisations possible, e.g. a two level table
- Concentrating (de)allocations in a portion of the bitmap has desirable effect of concentrating access
- · Simple to find contiguous free space

### Implementing directories

- · Directories are stored like normal files
  - directory entries are contained inside data blocks
- The FS assigns special meaning to the content of these files
  - a directory file is a list of directory entries
  - a directory entry contains file name, attributes, and the file i-node number
    - maps human-oriented file name to a system-oriented name.

31 JUNSW

31

### Fixed-size vs variable-size directory entries

- · Fixed-size directory entries
  - Either too small
    - Example: DOS 8+3 characters
  - Or waste too much space
    - Example: 255 characters per file name
  - Variable-size directory entries
  - Freeing variable length entries can create external fragmentation in directory blocks
    - · Can compact when block is in RAM

32 JUNSW

32

### Searching Directory Listings

- Locating a file in a directory
  - Linear scan
    - Implement a directory cache in software to speed-up search
  - Hash lookup
  - B-tree (100's of thousands entries)

### Trade-off in FS block size

- · File systems deal with 2 types of blocks
  - Disk blocks or sectors (usually 512 bytes)
  - File system blocks 512 \* 2^N bytes
  - What is the optimal N?
- Larger blocks require less FS metadata
- Smaller blocks waste less disk space (less internal fragmentation)
- Sequential Access
- The larger the block size, the fewer I/O operations required
- Random Access
  - The larger the block size, the more unrelated data loaded.
  - Spatial locality of access improves the situation
- Choosing an appropriate block size is a compromise
